Continuing with the Platine Verdier. The motor is sourced from philips but it is not just any run of the mill production motor. It is called a "Low inertia motor", In a low inertia motor the rotor consists of a copper coil; the turns almost parallel with the rotational axle cutting the field lines of the magnetic circuit, excited by a permanent magnet that is totally fixed. The magnets are metallic alloy and the brushes and collector are gold-plated. The rotor turns in fitted and self-lubricating bronze bearings. The motor is DC powered with a simple regulatory circuit that obtains perfect stability. Sometimes it is good to see why the very expensive belt-drives cost as much as they do.
