Of particular interest to me is the time domain rather than the frequency domain. It also seems people have sensitivities in one or the other. Other interesting things such as Low Q resonances being more audible than high Q ones. One thing is for sure - The room and loudspeakers contribute the most distortion. As for the rest well, you can do your own blind testing but certain smart a**s may dismiss the results. Does it matter if they do? Just like politics and religion, such is audio _ it gets people passionate.
