What a whallop that thing must put out! I realized when reading your post that your new horn with the high-power driver might generate more than 10dB greater than the old one. My thinking in my last reply to you was that with the greater power, there would also be a little more compression. But this overlooks the fact that the original driver would suffer from compression too, and maybe (probably) more than the better one. I hope all your interior trim pieces are well attached. But I'll bet they don't stay that way!
