Hey-hey!!!, There are other inexpensive front end pentodes to use. 6AQ5 is one suspect. Put g2 at 100V for a 10k load and 300V B+. 6CL6 would want a little bit less(if the curves are to be trusted), say ~80V. The 6AQ5 would cut gain by half due to lower gm, and 6CL6 by maybe a fifth. EF184 data I have found does not show anode current at $g_1=0$ and varying g_2 , but it would offer slightly higher gain than the 12BY7. Guidelines only, play and see how they sound. cheers, Douglas
