I was wondering what are some common causes of resonance. I have a set of Paradigm Monitor 70p's and one of the speakers resonates whilst playing some of my favorite piano tunes. I took my speaker back and the tweeter diaphragm was replaced. Despite this repair the speaker still resonated, but to a lesser extent. I took the speaker back in for repairs after I showed the tech what the problem was and let him listen to the speaker. It was suggested that the amp be replaced, as they are powered towers. I was told that the speaker was sent back to the factory for repairs. Could it be that this one speaker was a bad one that got out in the world with a defective cabinet and/or drivers?
