Do like I'm doing. Take your horns, with the driver attached, to a local university engineering department and talk to the NVH prof (noise, vibration, and harshness) and have do an "experimental modal analysis" on the horn and driver. That will tell you the resonant frequency of the horn/driver and from there they can tell you what freq your dampening stuff should be and where to get it. With this method you can make a horn/driver combo as dead as concrete (which by the way has a resonant freq but is too low to notice)
