Hi Wayne, I think I understand how to calculate values of L and C to simulate mechanical reactance in SPICE. R of L and C = Z_{max}/Q_{ms} at $F(res)$. However, looking at your examples of woofer models in the crossover document on your site, it seems to assume that $Z_{max} \sim 10 \times Q_{ms}$ for all drivers. This would be correct for the Alpha8, but does not match the specs available for the other drivers. Can you please clarify? Also, is the R value in the mech reactance model set at Z_{max} ? thanks, gar.
