Sorry, I didn't see this post until now. Don't know how I missed it.

The LMS system is great for doing outdoor sweeps. It is rock solid and dependable, I can always trust its results. I also like the tool that produces polar charts from a series of off-axis response curves.

However, for development work, I like the S&L system better. It has so many built-in tools. The T/S measurements are reliable and easy to use. The WTPro also has the ability to go a step further, to allow you to measure the speaker in the box and to tell you the anechoic response. It's a handy way to know what the loudspeaker will do in terms of bass response without having to lug it outside. You can then design the crossover with the help of the ICD. The WTPro is a very useful development tool.
