That response curve does look nice. The first thing I notice is probably a show-stopper though. The throat area is tiny, so small it will probably cause problems. It's hard to say without measurements, since this is a midrange horn, but generally that small of a throat is hard on cones.

You might also want to check the sizes of the front and rear chambers, to see if they are physically possible. Sometimes you find a really great set of parameters in a modeler that aren't realizable in practice because of physical constraints. So watch out for that too.
