Took another look at the SB Acoustics page and found that its recommended for use up to 1 KHz... My immediate thought is... "what if we change the crossover to 1 KHz, with a BMS 4550 CD playing through a H290 Horn?"

Because of the new crossover point, the spacing between the woofer and horn will now have change for optimal response in the vertical plane, is it not? Can this optimal spacing be reasonably predicted without extensive testing?
