Hey-Hey!!!,The pentode can do quite a good job. Free from Miller capacitance issues. The g2 supply is critical, \*VERY\* critical I suspect. The load line must be done quite carefully so as not to run through the curves through below the horizontal( or comparatively so )plate lines. With reasonable B+ this usually means a fairly low resistor values. 20k-40k depending on there you put the g2 voltage.regards,Douglas
