The sandbags were on top of the speakers lol.

My crown amps use 3rd order slopes, which is also considered a little steep, but I have no trouble blending them with my 4pi mains.

Sometimes there is more to it than just the crossover slope.

My old scan speak subs used plate amps with second order slopes, yet there was really no blending them with the mains if low passed above around 50Hz.

I still think the passive radiator design was the problem with those muddy sounding subs.

I have read on masonry occasions that passive radiator subs are not good for low passing higher than 70/80 Hz. I could not even cross them that high.
