In a home hifi system, I often read about how a tube amp (generally) likes a "resistive load".

I'm assuming the loudspeaker usually presents this load?

Is it due to the overall loudspeaker impedance (and its curve)?

The passive crossover components? A combination of these, or none?

I'm certainly generalizing here (or perhaps completely off base)....

so I'm interested in learning more about it.

Any input (or links to the subject) appreciated!
