Hy again Wayne . Im considering to make only 1 round port (I sum the three rectangular areas of the front ports) and calculated a round port of $4 \frac{5}{8}$ in the back of the 8 pi cabinet .my question is what if i throw the port into the corner of the room near a few inches could have a gain instead of the three front ports firing into the open room . thanks

You can make the port in a different shape, and position doesn't matter as long as it doesn't cause standing wave pipe behavior. Corner loading works at bass frequencies several feet away from the apex, so a port on the front of a corner-loaded speaker will act the same as one on the back unless the speaker is several feet deep. When a sound source is placed at the apex of a trihedral corner, it radiates purely into eighth-space. The walls of the corner define the radiating angle. In this situation, the walls don't act as reflectors because a wavefront travels along them or away from them rather than towards them and reflected by them. When a sound source is near a boundary, then it confines the radiating area and also acts as a reflector. At low frequencies,

woofers and ports can be placed fairly far away from corners and still radiate into eighth-space.

Standing waves are what give a pipe organ its sound. The length of each pipe tunes its

frequency. This is also the principle at work in transmission lines. Reflex cabinets, transmission lines and basshorns
