So I'm looking at the curves for the Alpha 10 and the Vifa tweeter in the 2pi Studio and Note that the Aplha 10 has an 8 ohm impedance and the tweeter has a 4 ohm nominal. I'm confused as to why there is a difference in impedances. What is happening electrically and why? Does this somehow induce a taper in the upper frequencies?

has a benign impedance curve and is a very easy load for an amplifier to drive.
