Hi,I'm new in this forum.I have Lowther PM7A and will add front horn (Azura) to it soon. The Horn supposed to be good down to 200-300Hz.I would need bass module. I prefer not too big (around 100 liter max). I doesn't need to go to 20Hz, I think 40Hz would be good enough. Sensitivity is not that crucial since I will bi amp the woofer, but more important is the bass to "fast" enough to keep up with the horn and can integrate seamlessly.Would 3pi sub suitable? or maybe pi4 with JBL 2226?Thank you in advanceRegards

vocal range. I think you'll find it to be a good match.

Those are external dimensions.

The Delta 12LFA is an excellent sounding woofer. It is full sounding and does a great job of putting out the bass without sounding bloated. No notes are overemphasized, nor are there any suckouts. But it doesn't have a shorting ring like the JBL 2226 does. That makes the JBL much cleaner sounding and more articulate.

Please excuse my ignorance, what are these bass modules? Lots of people are talking about them but they are not listed on the website?

Oh I see. So what do people use for the tweeter/midrange? Just conventional speakers? And how do you bend the bass module with the main speakers? With active crossover and bass amp? So basically just use them as subwoofers? This is an interesting idea as I am building the 3pi with externally placed tweeters. I may try to use the bass module as subs for my main speakers.

Usually people build or buy completed loudspeakers. Occasionally, someone already has a favorite full range horn or something, and they just need a bass bin that operates up through the

tweeter. Whether a standard model is used or some kind of hybrid, the bass is good and most people don't augment their speakers with a sub. Room gain tends to lift the very deepest bass, so a gradual rolloff is desirable in many cases. However, in large rooms or in other situations where a sub is desired, one of the dedicated subwoofers can be used. Dedicated subs are tuned differently than a full-range model. The woofers chosen for the subs are designed to be used between 20-200Hz, and the cabinet is tuned for this range also. In contrast, woofers chosen for full-range models are designed for a much higher bandwidth, but don't go as deep. If you need a midwoofer

in the midrange and bass goes pretty deep. Rolloff is gradual and smooth, making it a nice compliment to room gain. On the other hand, if what you're interested in is to augment the very deepest bass frequencies, then a subwoofer is better. It can be used down to 20-30Hz. A dedicated sub should be crossed over no higher than 100Hz for best integration. Any higher and you will be able to hear the sub as distinct speaker, which is not what you want. You want a subwoofer to add a foundation, but not to call attention to itself. It should not be louder than the rest of the system, nor should it "thump". If done right, no one can tell the subwoofer is on, it just sounds like the mains go deeper in bass.

Thanks for your explanation. I don't really need deep deep bass, but adding another 10-20 hz to my merlin tsm monitors will be great. Since I am building the 3pi anyway, able to run the bass bin with other speakers as well as a full range with the tweeters is a plus and just add more fun. I am really looking forward to receiving the kits and completing the speakers. Such a new and exiting journey for me!Thanks again!
