Mild case A.S.D. is statistically over-represented in the Science and Engineering disciplines. A new study done at Stanford shows a very staistically high incidence of this trait in the children of Silicon Valley. It has also been demonstrated that the A.S.D. catagory is not a syndrome but more of an alternate sensorial processing expressed non-pragmatically. Can this have some co-relation to the dis-connect between the measuring fanatics and the verbal construction fans? It would explain the whole dichotomy epidemiologically.
