I had a little hum in my GC so I tried this little fix and it seems to work. I went to the golf shop and bought some of the lead tape they use to wrap clubheads. It's about 5\$ a roll. I then lined it up on the wall between the transformer and the PC boards; overlapped it and ran strips down to the chassis. Hum is gone so far.

Wow, so the flux from the transformer was coupling over into the circuit. That's a good fix.

Thanks. I didn't have the room to place the trans further out.

Wow got to try that. I built one in an surplus power supply and have some hum. I didn't like it enough to fight with it. but hey I'll go \$5...John

For the price they are a good thing. I have slapped together a couple for freinds and they are very

happy; but it is true, they don't have any kind of magic. Smooth and clear but uninspiring. I started to build them because they were cheap and helped me to learn construction techniques; as well as offering an opportunity to see first-hand how changing caps and resistors affected the sound. After a long journey here and elsewhere sampling many amps/tweaks/mods etc. I think I have come full circle. The older Loftin-white/WE 91/Mullard etc. tube amps are the amps that do music best. The arguments that chase their tail about rolled off extremes and harmonic distortion are utterly useless in describing music and sound. Most of the people who stand behind the spec group are mostly listening to highly processed reproduced CD's and Vinyl and as such cannot enjoy real tone and life in the equipment because it reveals this badly engineered sound. Good older tube based recordings are the only way to understand sound; and they don't do well on flat/etched/hyper-revealing equipment. That's why I dropped the SS experimentation for now.
