I've not seen it in production. I would expect something like this to modify cone breakup behavior, so the upper response could be tuned. But I don't see how IM distortion is improved unless bandwidth is reduced. I also don't think it would work on a horn because it is too small to be significant at the low frequencies where the horn is most reactive.

Did you read the patent. It seems to have solid theory. Regards Tim

I did read the patent, but I don't think much of it.

OK, send. If you have some webspace, you could probably upload to it and post a link.
